DESIGN INITIATIVE & TARGET USER

University students who take part in campus meal plans are the system's main users. Near the end of the semester, many students have unused meal swipes, while other students might run out of swipes and require extra meals. Students who have extra swipes can use this system to make listings and sell or donate their extra swipes to other students in need.

Users can participate in this market as buyers or sellers. The number of swipes available, price, preferred dining hall location, and degree of urgency are all listed by sellers. In addition to browsing available listings, buyers can start transactions with sellers and filter results according to their preferences. Reducing wasted meal swipes and facilitating students' access to reasonably priced meals are the goals of the system.

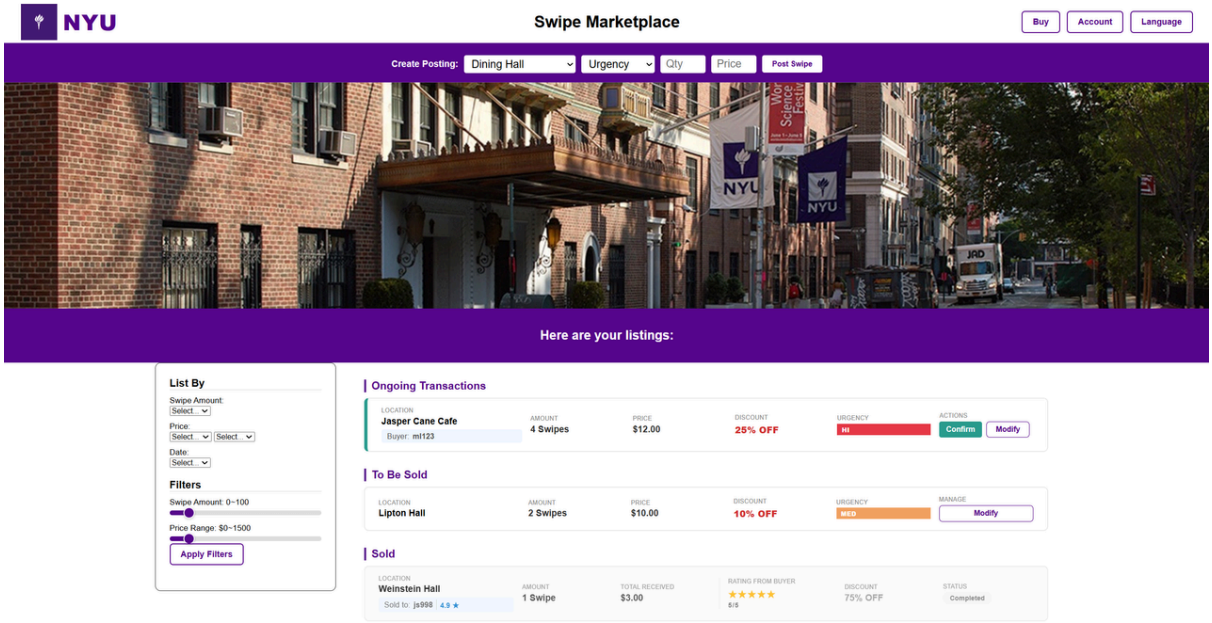
DESCRIPTION OF CHOICE

A web-based graphical user interface (GUI) will be used by our system. Without installing any extra software, users can access the meal swipe marketplace using a standard web browser using web application. A web-based system gives students an easy-to-use platform to browse listings and handle transactions, as the majority of university students regularly use laptops or mobile devices with internet access.

We decided on a web interface because it facilitates simple integration with backend databases, cross-platform compatibility, and easy deployment. From any internet-connected device, users can easily create listings, see available meal swipe offers, and handle transactions. Additionally, this design makes it simple to update or expand the system in the future without requiring users to install new application versions, solving the annoying updating issues.

INTERFACE & UI ELEMENT EXPLANATION

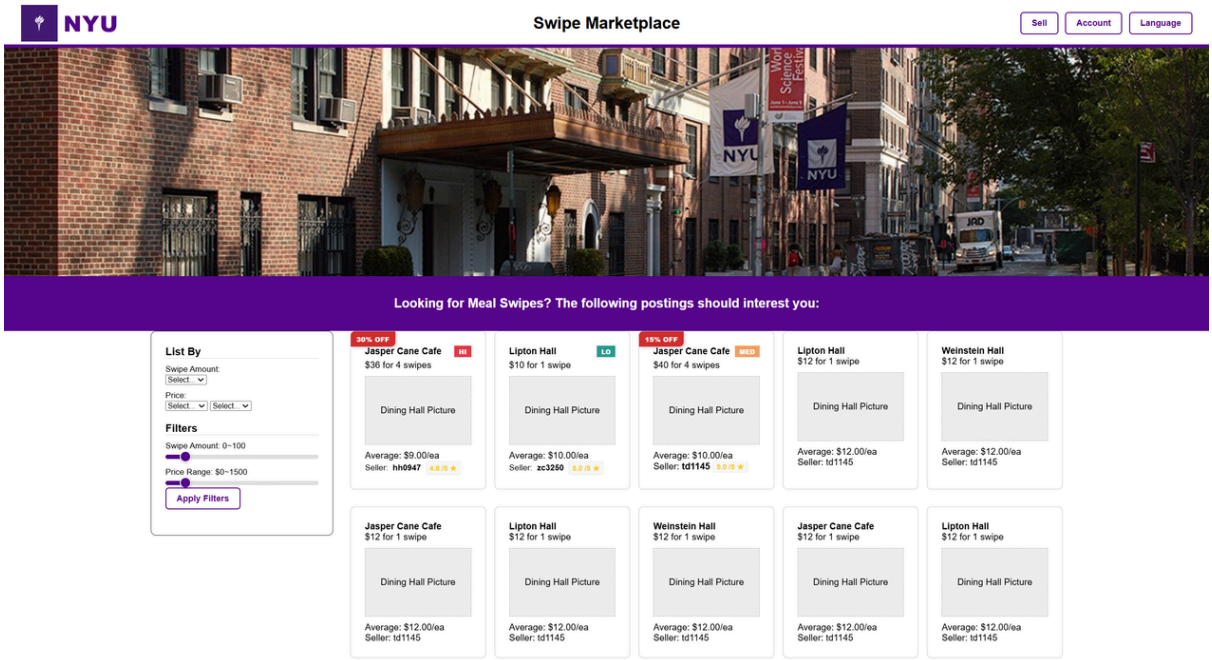
Selling Page



This screen is where users manage selling their meal swipes. At the top of the screen, there's a navigation bar where users can jump between the buying page, their account settings, and language preferences. Right under the navigation bar, the posting bar lets sellers quickly put up new listings. They just pick the dining hall location, urgency level, swipe quantity, and price, then hit the "Post Swipe" button to submit it. On the left side of the screen, there's a filter panel where users can sort listings by swipe amount, price range, and date using dropdown menus and sliders. These filters make it easier for users to find and sort through listings.

The main part of the dashboard shows the seller's listings along with their transaction details. The ongoing transactions section displays listings with active buyers right now and gives info like location, swipe amount, price, discount, urgency level, and buyer details. Sellers can use the action buttons to confirm or change transactions. The "To Be Sold" section shows all the active listings that haven't been sold yet, so sellers can update them whenever they need to. The sold listings section shows a record of past transactions, including buyer ratings and the status of each sale, so sellers can look back at how their previous sales went.

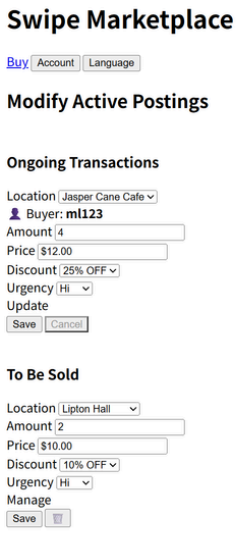
Buying Page



This screen shows users looking for meal swipes a list of available offers posted by sellers. Listings appear in a card-style layout that includes important details like the dining hall location, number of swipes, total price, average price per swipe, and the seller's ID and rating. Some listings show discount labels and urgency signs that help buyers spot better deals or listings needing quick action.

On the left side of the screen, there's a filter panel where buyers can narrow down the listings by things like how many swipes they want and the price range. Buyers can find listings that fit what they want by tweaking these filters and using them. The layout lets users quickly look at several listings side by side and pick the one that fits best.

Listing Modify Page



This screen lets sellers change the details of their active listings or current transactions. The page has input fields and dropdown menus where users can update listing details like the dining hall location, number of swipes, price, discount level, and urgency level. These fields match the attributes in the listing database records and let sellers change their listings when conditions shift.

At the bottom of the form, users have the option to either save their changes or cancel them. The save button updates the listing information in the system, and the cancel button discards any changes and takes the user back to the previous page. This interface gives sellers an easy and flexible way to manage their listings and keep their marketplace info accurate.
